

Figure C. Longitudinal bathymetry along the Kamaishi Regional2D corridor

Bed elevation sampled along the corridor centreline from the offshore event region toward the selected wet nearshore interface.

Offshore long-wave propagation

Depth-averaged, approximately hydrostatic tsunami propagation is efficiently represented by the Regional2D NLSWE model.

Region boundaries are interpretive rather than fixed physical thresholds; the selected wet nearshore interface is the current case-specific 2D->3D extraction location.

Profile: R10 h400 corridor-centreline sampling; bed elevation referenced to EGM2008. $b_c(s)=b(x_c(s),y_c(s))$.

Shelf / shoaling influence

Decreasing water depth and changing bathymetry increasingly modify wave celerity, amplitude and waveform toward the coast.

Nearshore transition

Increasingly local free-surface deformation, vertical motion and structure interaction motivate transfer toward high-fidelity Local3D impact modelling.
